He states that there's no known reason why a species couldn't live forever. This is fallacious since the world is constantly changing and species must adapt or go extinct. There's no such thing as a "bad gene", there are only genes which survive change, or don't. When enough don't the species disappears.

Scientists agree on the fact of extinction, but science has never agreed on its physical causes. From the traditional theory of climate change to the controversial theory of meteorites, David Raup investigates each possibility. Questioning much of conventional wisdom, he makes a number of startling new claims. From the publisher's announcement:

fitness (or adaptiveness of the organism) and that extinction of a given species or higher group is more bad luck than bad genes. The conclusions I will reach are not definitive but I hope the exercise will stimulate further exploration of the problem from fresh points of view and with fresh methodologies.

He concludes, "Extinction is evidently a combination of bad genes and bad luck. Some species die out because they cannot cope in their normal habitat or because superior competitors or predators push them out. But, as is surely clear from this book, I feel that most species die out because they are unlucky.

One of the greatest unmet challenges in conservation biology is the genetic management of fragmented populations of threatened animal and plant species. More than a million small, isolated, population fragments of threatened species are likely suffering inbreeding depression and loss of evolutionary potential, resulting in elevated extinction risks. Although these effects can often be reversed by re-establishing gene flow between population fragments, managers very rarely do this. On the contrary, genetic methods are used mainly to document genetic differentiation among populations, with most studies concluding that genetically differentiated populations should be managed separately, thereby isolating them yet further and dooming many to eventual extinction! Many small population fragments are going extinct principally for genetic reasons. Although the rapidly advancing field of molecular genetics is continually providing new tools to measure the extent of population fragmentation and its genetic consequences, adequate guidance on how to use these data for effective conservation is still lacking. This accessible, authoritative text is aimed at senior undergraduate and graduate students interested in conservation biology, conservation genetics, and wildlife management. It will also be of particular relevance to conservation practitioners and natural resource managers, as well as a broader academic audience of conservation biologists and evolutionary ecologists.

Fifty years ago, no one could explain mountains. Arguments about their origin were spirited, to say the least. Progressive scientists were ridiculed for their ideas. Most geologists thought the Earth was shrinking. Contracting like a hot ball of iron, shrinking and exposing ridges that became mountains. Others were quite sure the planet was expanding. Growth widened sea basins and raised mountains.

There was yet another idea, the theory that the world's crust was broken into big plates that jostled around, drifting until they collided and jarred mountains into existence. That idea was invariably dismissed as pseudo-science. Or "utter damned rot" as one prominent scientist said. But the doubtful theory of plate tectonics prevailed. Mountains, earthquakes, ancient ice ages, even veins of gold and fields of oil are now seen as the offspring of moving tectonic plates. Just half a century ago, most geologists sternly rejected the idea of drifting continents. But a few intrepid champions of plate tectonics dared to differ. The Mountain Mystery tells their story.

A readable account of the history of natural disasters throughout history.

Chronicling five times in the history of the earth in which more than half of all living species disappeared in a geological instant, a geological study states that we are on the brink of a sixth mass extinction and presents supporting evidence. Reprint.
